- 7 Appendix

Motivation

Motivation

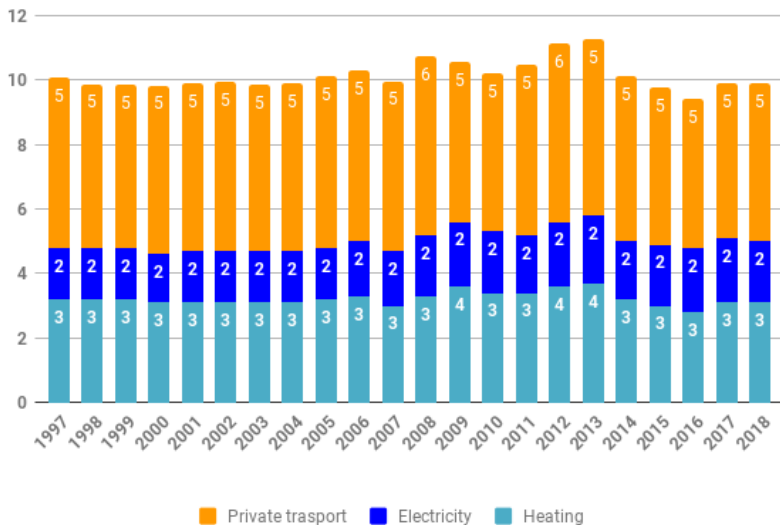

- understanding energy demand is crucial for energy and climate goals;
- poor evidence of the distributive effects of carbon pricing in Italy.

Main results

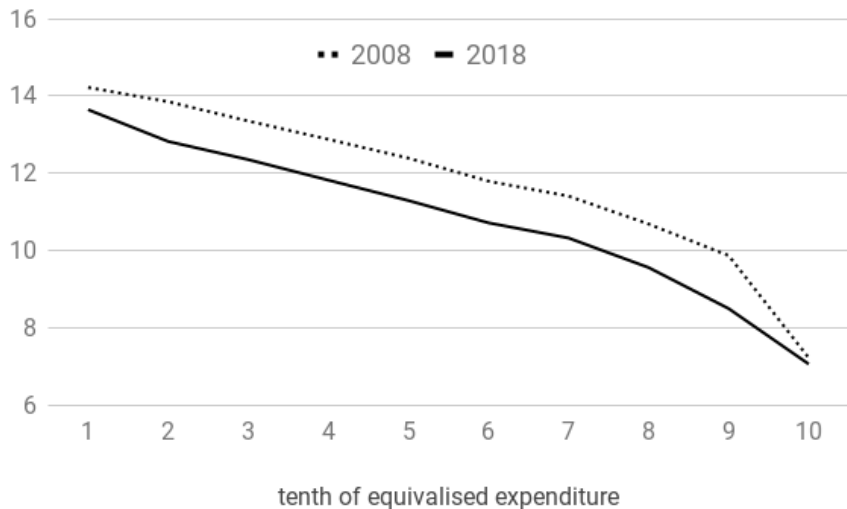

- we develop a microsimulation model for HHs energy demand in Italy;
- short run demand is inelastic; long run demand is elastic;
- a carbon tax will significantly affects HHs, especially energy poor, abate up to 13% of total emissions and raise up to € 15.5 billion;
- revenue-recycling to mitigate effects on more vulnerable households (and increase policy acceptance).

Descriptive statistics and data

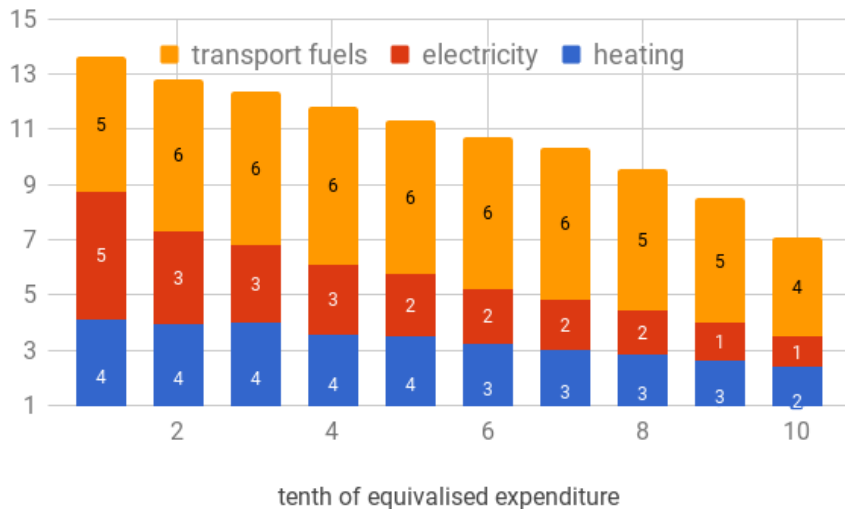

Share of expenditure by energy use

Energy share by tenth of expenditure: 2008 vs 2018

Energy share by tenth of expenditure in 2018

Data

- Italian Household budget survey (HBS) from Istat (1997-2018); ~ 16-20.000 obs per year;
- semi-annual retail electricity and natural gas prices from Eurostat;
- price components from ARERA;
- monthly gasoline and gasoil prices from MISE;
- HICP from Istat;
- wholesale electricity (PUN) and natural gas (PSV) prices and Brent from Bloomberg;

Identification strategy

Identification strategy

- HBS is a cross section study, not a panel;
- *quasi*-panel (Deaton,1985);
- *strata*: (9) household type (from Istat) \times (4) quartile of the equivalent expenditure distribution = 36 strata;
- 36 strata \times 22 years \times 12 months = \sim 9.500 obs

Estimating energy demand

for each household i at time t

$$S_{i,t}^E = \frac{(E^E_{i,t} + E^H_{i,t} + E^T_{i,t})}{Exp_{i,t}} \quad (1)$$

where

- E^E is the electricity expenditure;
- E^H is the heating expenditure;
- E^T is the private transportation expenditure;
- Exp is the total expenditure.

Estimating electricity (heating) demand

$$E_{i,t}^E = (P_{i,t}^{vE} Q_{i,t}^E + P_{i,t}^{fE})(1 + T_t) \quad (2)$$

where

- $P_{i,t}^{vE}$ is the variable price per kWh (Gj for natural gas);
- $Q_{i,t}^E$ is the quantity of electricity demanded (unknown);
- $P_{i,t}^{fE}$ is a fixed price component;
- $(1 + T_t)$ are taxes (VAT).

Solving for $Q_{i,t}^E$, it follows

$$Q_{i,t}^E = \left(\frac{E_{i,t}^E}{1 + T_t} - P_{i,t}^{fE} \right) * \frac{1}{P_{i,t}^{vE}} \quad (3)$$

All quantities are calibrated

Estimating private transport demand

- In Italy there are 3 fuels used for private transportation: gasoline, gasoil and LPG/CNG ($\sim 9\%$). Up to 2014, data on Gasoil and LPG/CNG expenditures are merged;
- In the bottom tenth less than two thirds of the households owns a cars while in the top tenth, 9 out of 10 households possess a private vehicle;
- retail price is competitive (more than 15k fuel pumps);

$$Q_{it}^T = \frac{E_{i,t}^G}{P_t^G} + \frac{E_{i,t}^D}{P_t^D} \quad (4)$$

where

- E^G and P^G are gasoline expenditure and price;
- E^D and P^D are diesel expenditure and price;

All quantities are calibrated

Estimating elasticity

We take average demand by *strata* and we estimate the (short and long run) price and income elasticities separately for three energy services $z = E, H, T$:

$$\log Q_{s,t}^z = \lambda_s \log Q_{s,t-1}^z + \beta_s \log P_{s,t}^z + \gamma_s \log E_{s,t} + w + s + t + t^2 + \epsilon_{s,t} \quad (5)$$

- a lagged term, $\log Q_{s,t-1}^z$;
- the (real) price of the fuel ($\log P_{s,t}^z$);
- household' total expenditure ($\log E_{s,t}$);
- a set of time trend (t and t^2) and seasonal dummies (w for autumn and winter months and s for summer).

Estimating elasticity - further issues

- short vs. long run elasticity
 - we fit an autoregressive distributed lag (ARDL) or partial adjustment model;
 - long-run elasticity = $\frac{\beta_s}{(1-\lambda_s)}$ (Greene, 2008);
- endogeneity of $\log P_{s,t}^Z$;
 - 2SLS estimator;
 - electricity: day-ahead price ("Prezzo unico nazionale" or PUN);
 - heating: price set at the Virtual Trading Point ("Punto di scambio virtuale" or PSV);
 - liquid fuels: spot price (free on board) for the European Brent.

Results

Results: short and long run price elasticities

	Short run price elasticities			long run
	LS	stratum-level LS	2SLS	
Electricity	-0.36***	-0.29*	-0.40***	-1.17***
Heating	-0.40***	-0.44**	-0.44***	-1.23***
Transport	-0.17**	-0.45**	-0.66***	-1.46***

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

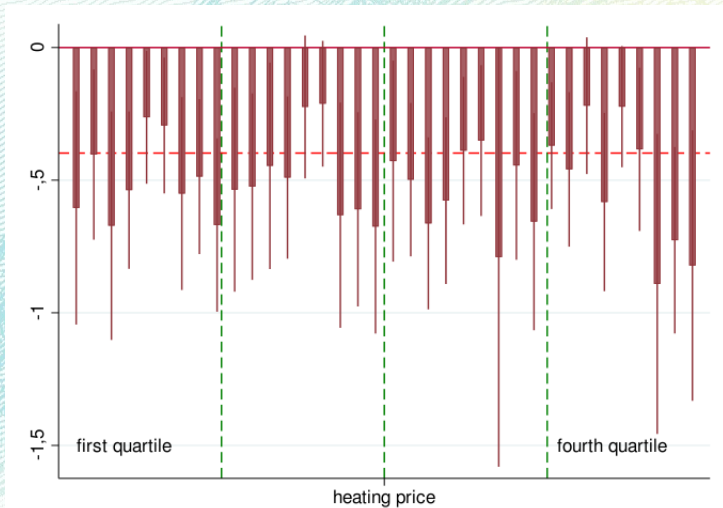

Robustness checks:

- (robust) test for endogeneity (Wooldridge, 1995): strongly reject exogeneity only in Transport;
- test for weak instruments: Cragg-Donald/Stock and Yogo (2005) approach unfeasible; F-stat > 104 (Lee et al 2020) in all cases;
- Im-Pesaran-Shin test (2003) reject the null hypothesis of non-stationarity

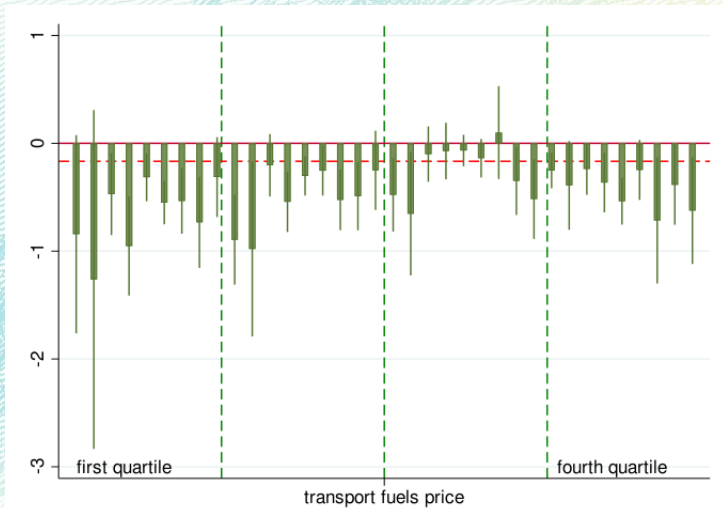

Short run price elasticity of electricity by stratum

Short run price elasticity of heating by stratum

Short run price elasticity of transport fuels by stratum

An application: a carbon tax in Italy

Carbon pricing as an optimal tool

- A global carbon price is the economists' recommended choice to tackle climate change (Tirole, 2017);
- though there are several methodological issues on identifying the "right price" (see Pindyck 2013 and 2017; Cortes et al. 2020);
- two types of carbon pricing: set Q (ETS) or P (carbon tax);
- currently 64 carbon pricing initiatives in place, either ETS (29 initiatives, 16% world GHG covered) or carbon tax (35 initiatives, 5.5% GHG - World Bank, 2021);
- In EU-27 + Iceland, Liechtenstein and Norway, the EU-ETS covers 45% of all the GHG emissions; local schemes (e.g. Sweden carbon tax) exist in half of the member states.

A carbon tax in Italy

- Italy belongs to the EU-ETS; currently, there is no national carbon pricing scheme;
- we choose to focus on 4 possible CTs: €50 (current EU-ETS), €100 (COP21 compliant), €200 and €800 (peak values *orderly* and *disorderly* NGFS scenarios);
- we use the specific carbon emission factors from official sources for each fuel to estimate the impact of each carbon tax on final energy prices;

carbon emission factors per fuel
ton CO₂ per GJ

Electricity	Heating	Petrol	Diesel
0.078167	0.055820	0.067903	0.068301

Effects of the CT on final energy prices

€ per ton of CO ₂	Carbon taxes			
	50	100	200	800
Price variation				
Electricity	+6.3	+12.6	+25.2	+100.8
Heating	+11.8	+23.6	+47.2	+188.7
Transport fuels	+7.9	+15.9	+31.8	+127.2
% change compared with the baseline year (2018)				

Using 2018 prices as baseline, the introduction of a carbon tax of e50 per ton, is equivalent to add: €0.014 to each kWh of electricity; €2.8 to each GJ of gas and €0.12 to each litre of gasoline or gasoil.

Adjustment to our microsimulation model

Use price variations and previously estimated elasticities to get new demand:

$$\hat{Q}_{is|(\tau=CT)}^z = \hat{\beta}_s * [\log P^z * (1 + \tau_{CT}^z)] + \hat{\epsilon}_s \quad (6)$$

where

- $\hat{\beta}_s$ are the estimated elasticity for each stratum s ;
- is the implied price changes τ_{CT}^z ;
- $\hat{\epsilon}_i \sim \mathcal{N}(0, RMSE_i)$

...and new, counterfactual, total expenditure:

$$Exp_{is|\tau=CT} = Exp_{is} + (E_{is|\tau=CT} - E_{is|\tau=0}). \quad (7)$$

Results of the simulations (1 out of 2)

€ per ton of CO2	Carbon taxes			
	50	100	200	800
Energy demanded				
Electricity	-1.7	-3.4	-6.3	-19.6
Heating	-5.1	-9.7	-17.7	-48.1
Transport fuels	-2.6	-5.1	-9.5	-28.3
Total energy demand	-4.2	-7.7	-13.8	-38.0
Expenditure				
Electricity	+4.5	+8.9	+17.3	+61.6
Heating	+6.6	+12.6	+22.9	+54.1
Transport fuels	+5.1	+10.0	+19.2	+62.6
Total energy expenditure	+5.4	+10.6	+20.0	+59.8
Total expenditure	+0.5	+1.0	+2.0	+5.9

Results of the simulations (2 out of 2)

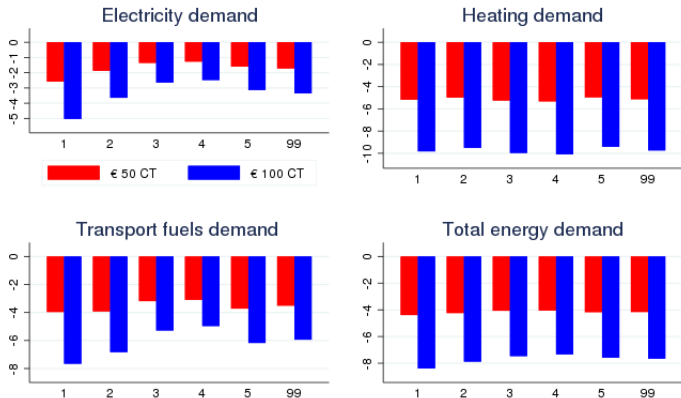

€ per ton of CO2	Carbon taxes			
	50	100	200	800
Effect on inflation (2018)*	+0.7	+1.4	+2.8	+11.3
CO2 Emissions and revenues				
% var	-3.7	-7.0	-12.9	-36.4
Emissions (Δ MtCO ₂ e)	-4.8	-9.3	-17.0	-48.0
Revenues (billion of €)	+4.2	+8.2	+15.5	+42.1

* Additional percentage points to the Italian consumer price index (NIC).

(Total GHG emissions in 2018: 438 MtCO₂eq - 112 from HHs)

Greater reduction in energy demand for poorer households

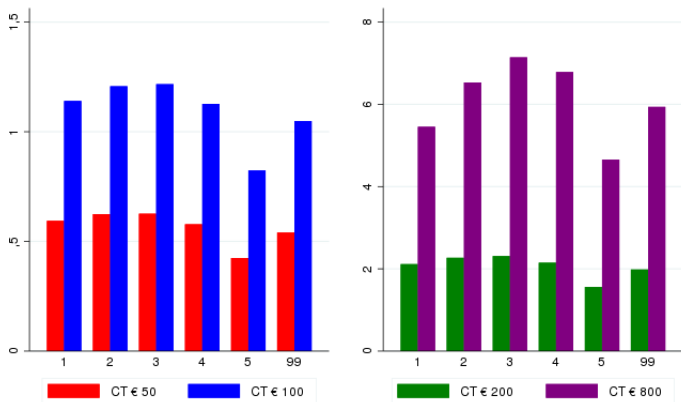

HHs energy demand under € 50 and € 100 CT: by exp. quintile
Change compared with the case of no CT

1= poorer households; 5=richer households; 99= all households

Carbon tax would be regressive

Total household exp. under different CT: by exp. quintile
Change compared with the case of no CT

1= poorer households; 5=richer households; 99= all households

Conclusions

Conclusions

- we develop a microsimulation model for energy demand in Italy;
- short run demand is inelastic; long run demand is elastic;
- a carbon tax will significantly affects HHs, especially energy poor, abate up to 13% of total emissions and raise up to € 15.5 billion;
- revenue-recycling to mitigate effects on more vulnerable households (and increase policy acceptance).

Thank you for your attention!

Appendix

Literature review on energy demand elasticities

- seminal paper Houthakker (1951); several works on electricity demand (fewer for other fuels);
- Taylor (1975): price elasticity for electricity is larger in the long run;
- Dubin (1984): two-step approach, so-called sequential discrete-continuous models;
- Espey and Espey (2004): meta-analysis of 36 papers, with more than 123 short-run and 96 long-run price elasticities estimates of residential electricity demand: short-run elasticities range between -2.01 and -0.004 (mean: -0.35) while long-run elasticities range between -2.25 and -0.04 (mean: -0.85).
- Labandeira et al. (2017): meta-analysis for a dozen *surveys* on energy demand; they report a -0.126 (-0.365) short (long) run price elasticity for electricity, -0.180 (-0.684) for natural gas, -0.293 (-0.773) for gasoline, -0.153 (-0.443) for diesel and -0.017 (-0.185) for heating oil.

Literature review - Italy

- Faiella (2011): effect of prices on the *shares* is negative for heating and positive for private transport. For electricity: negative (positive) for the 1997-2004 (2005-07) period;
- Bigerna (2012): the price effect of electricity depend on the time of the day (due to the tariffs system in place up to 2016, encouraging off-peak use) and on the geographical zones;
- Bardazzi and Paziienza (2019): electricity demand is hump-shaped w.r. to age of the RP (peak at 50 yrs); natural gas demand keeps increasing with age; price elasticities for electricity and natural gas are -0.705 and -0.621 respectively (higher in the Centre and in the Southern regions).
